Community reports need a reviewable path

For residents

A local concern should be reportable in the language and format a person can use, with a receipt they can refer to later.

For public-service teams

Submissions need a consistent workflow for review, status updates, and aggregate views that help teams notice where reports are coming from.

The platform supports staff judgement; it does not make binding public decisions.

One workflow for intake and staff review

1

Submit

A resident sends text or an audio recording through the API.

2

Receive

The backend stores the submission and returns a receipt.

3

Process

A background worker handles text; the mock classifier is the current default.

4

Review

Staff can inspect reports, update status, and view aggregate counts.

Audio intake works; transcription is not connected yet, so audio submissions go to staff review.

Architecture and implementation status

● Implemented in local backend ● Planned / not connected

Proposed hosting: Firebase Hosting · Cloud Run · Cloud SQL. These services are not deployed yet.

Human review keeps the system advisory

Staff review proposals

The API exposes a staff queue, status changes, classification corrections, and audit records for review actions.

Counts stay descriptive

Analytics return report counts by status or district. The API labels district totals advisory and does not adjust for population.

Originals remain central

The workflow is designed to retain original feedback alongside any future transcript or model proposal.

Expected value: make submissions easier to organize and review. Impact still needs to be measured with residents and service teams.

What the team can demonstrate today

Backend/API prototype

- 1 Submit sample text in Swagger
- 2 Show the returned receipt
- 3 Keep the worker running and inspect the proposal
- 4 Open the staff queue and analytics routes

Local API docs: 127.0.0.1:8000/docs

Remaining before a full product demo

Connect the teammate's ASR service.
Replace the mock classifier with Gemini or a deployed NLP service.
Deploy the API, database, and private audio storage.
Build and host the frontend.
